Received 16 March 2009/Returned for modification 2 May 2009/Accepted 11 September 2009

Aryl hydrocarbon receptor (AhR), a ligand-activated transcription factor, is known to mediate a wide variety of pharmacological and toxicological effects caused by polycyclic aromatic hydrocarbons. Recent studies have revealed that AhR is involved in the normal development and homeostasis of many organs. Here, we demonstrate that AhR knockout (AhR KO) mice are hypersensitive to lipopolysaccharide (LPS)-induced septic shock, mainly due to the dysfunction of their macrophages. In response to LPS, bone marrow-derived macrophages (BMDM) of AhR KO mice secreted an enhanced amount of interleukin-1β (IL-1β). Since the enhanced IL-1β secretion was suppressed by supplementing Plasminogen activator inhibitor-2 (Pai-2) expression through transduction with Pai-2-expressing adenoviruses, reduced Pai-2 expression could be a cause of the increased IL-1β secretion by AhR KO mouse BMDM. Analysis of gene expression revealed that AhR directly regulates the expression of Pai-2 through a mechanism involving NF-κB but not AhR nuclear translocator (Arnt), in an LPS-dependent manner. Together with the result that administration of the AhR ligand 3-methylcholanthrene partially protected mice with wild-type AhR from endotoxin-induced death, these results raise the possibility that an appropriate AhR ligand may be useful for treating patients with inflammatory disorders.

The aryl hydrocarbon receptor (AhR) is a member of the basic helix-loop-helix/Per-Arnt-Sim homology superfamily and is involved in the induction of drug-metabolizing enzymes and the susceptibility of cells to a variety of cytotoxicities induced by dioxins (9). AhR is a ligand-activated transcription factor activated by polycyclic aromatic hydrocarbons (PAHs), such as 3-methylcholanthrene (3MC) and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). Under normal conditions, AhR exists in the cytoplasm in a complex with Hsp90, XAP2, and p23 (22). After binding a ligand, AhR translocates into the nucleus where it dimerizes with its partner molecule, AhR nuclear translocator (Arnt), and acts as a transcriptional activator to regulate the expression of target genes, such as those expressing drug-metabolizing cytochrome P450 (Cyp1a1, 1a2, and 1b1) and NAD(P)H:quinone oxidoreductase (Nqo), by binding to xenobiotic response element (XRE) sequences in their promoter regions (9). By using AhR knockout (AhR KO) mice, it has been demonstrated that AhR is essential not only for the induction of drug-metabolizing enzymes but also for most, if not all, of the toxicological effects caused by TCDD, including immunosuppression, thymic atrophy, teratogenesis, and hyperplasia (6, 7, 17, 24), the mechanisms for which are largely unknown. Recently, careful investigation into the loss of functions in AhR KO mice has also revealed that AhR is involved in the normal development of several organs, including the liver, heart, vascular tissues, and reproductive organs (1, 2, 6, 8, 15, 24). In addition, AhR has been found to play a key role in the differentiation of regulatory T cells Treg, Th17, and Th1 from naive CD4 T cells by regulating their expression of Foxp3 or by as-yet-unknown mechanisms (14, 20, 23, 32). From these studies, one of the general features of AhR that begins to emerge is that it serves as a multifunctional regulator in a large number of areas, ranging from drug metabolism to innate immunity for protection against invasive xenobiotics. In the work presented here, we demonstrated that AhR KO mice were hypersensitive to lipopolysaccharide (LPS)-induced septic shock, mainly due to the dysfunction of their macrophages. AhR KO mouse macrophages secreted an enhanced amount of interleukin-1β (IL-1β) in response to LPS treatment and had markedly reduced Plasminogen activator inhibitor-2 (Pai-2) mRNA concentrations, as revealed by DNA microarray analysis. Pai-2 was reported to be a negative regulator of IL-1β secretion through its inhibition of caspase-1 (10), suggesting that the enhanced secretion of IL-1β by AhR KO macrophages in response to LPS may have been due to the reduced level of Pai-2. We showed that AhR directly regulates the expression of inhibitory Pai-2, in an LPS-dependent manner, through a mechanism involving NF-κB but not Arnt.

MATERIALS AND METHODS

Mice. AhR knockout (AhR KO) mice were generated as described previously (17). These mice were back-crossed with C57BL/6J mice at least 10 times. Age-matched mice (10 weeks) were intraperitoneally injected with 20 mg of
At this point, no IL-1 ELISA (Biosource). and their culture supernatants were assessed for cytokines using a mouse IL-1 β inhibitor VI; Merck) or 100 µM Z-VAD-FMK (caspase inhibitor VI; Merck) for 30 min before LPS (10 ng/ml) stimulation. The BMDM were incubated for 8 h, and their culture supernatants were assessed for cytokines using mouse TNF-α and IL-1 β inhibitors. AhRflox/flox::LysM Cre and AhR KO mice. Mouse survival was checked every 6 or 12 h. 3MC (Wako, Osaka) at 10 or 50 mg/ml 3MC/g of body weight or 100 mg/ml 3MC in 0.5 ml saline (PBS) three times. For cytokine assays, washed cells were collected with a scraper, plated at 2 × 10⁶ cells/ml in 96-well plates, and cultured with 10 ng/ml LPS for 8 h.

Isolation of peritoneal exudate macrophages (PEMs). Mice were intraperitoneally injected with 2 ml of 4% thioglycolate. Peritoneal cells were isolated from exudates of the peritoneal cavity 3 days after injection, incubated for 3 h in appropriate plates, and washed with PBS. The adherent cells were used for experiments.

Measurement of cytokines. Mice were intraperitoneally injected with 20 mg/kg LPS and bled 2 h after injection. Plasma concentrations of IL-1β, tumor necrosis factor alpha (TNF-α), IL-6, gamma interferon (IFN-γ), IL-12, and IL-18 were determined by enzyme-linked immunosorbent assay (ELISA) (Biosource). BMDM of mice with wild-type AhR (AhR WT mice) and AhR KO at 2 × 10⁶ cells/ml were incubated with 10 ng/ml LPS for 10 h. The culture supernatants were assessed for cytokines using mouse TNF-α and IL-1β ELISAs (Biosource).

Cell culture. All cells were maintained in RPMI medium (Sigma) supplemented with 10% fetal bovine serum (HyClone) and penicillin/streptomycin (Gibco) under 5.0% CO2 at 37°C.

Caspase inhibitors. BMDM of AhR KO mice at 2 × 10⁶ cells/ml were incubated with dimethyl sulfoxide (DMSO) or 80 µM Z-YVAD-FMK (caspase-1 inhibitor; VeMerk) or 100 µM Z-VAD-FMK (caspase inhibitor VeMerk) for 30 min before LPS (10 ng/ml) stimulation. The BMDM were incubated for 8 h, and their culture supernatants were assessed for cytokines using mouse TNF-α and IL-1β ELISA (Biosource).

Virus infections. Adenoviruses expressing green fluorescent protein (GFP), human Pai-2 (hpai-2), and human Bel-2 (hbcl-2) were purchased from Vector Biosails (Philadelphia). BMDM from AhR KO mice were infected for 12 h with adenoviruses expressing GFP, hPai-2, and hbcl-2 at a multiplicity of infection of 100. Infected BMDM were washed with PBS, followed by 12 h of incubation. As it was reported that adenosviral vectors enhanced IL-1β secretion in macrophages (19), IL-1β levels were investigated in these incubation supernatants by ELISA. At this point, no IL-1β was observed in the supernatants. Therefore, the cells were washed, collected with a scraper, and plated at 2 × 10⁶ cells/ml in 96-well plates. The cells were treated with 10 ng/ml of LPS for an additional 8 h.

Retroviral infection was performed as follows: qpcM-AhR, a murine AhR (mAHR) fragment in pQCXIN (Clontech), and pQCXLN for LacZ expression (as a control) were transferred into 293T cells that were then cultured for 24 h. The culture medium was replaced with fresh medium, and the culture was continued for an additional 24 h. This culture medium was used as the retrovirus particle source.

Microarray analysis. Total RNA samples were purified using Isogen before being processed and hybridized to Affymetrix mouse genome 430 2.0 arrays (Affymetrix). The experimental procedures for the GeneChip analyses were performed according to the Affymetrix technical manual.

Generation of stable transformant cell lines. ANA-1 cells were the kind gift of L. Varesio (3). ANA-1 cells were transfected with LacZ- or AhR-expressing retroviruses in a suspension with 8 mg/ml of Polybrene. One day after infection, the infected cells were replated and cultured in a selection medium containing 0.5 mg/ml of Geneticin (Gibco).

Plasmids. pcDNA3-p65 and pcDNA3-AhR were generated by inserting AhR and p65 DNA fragments, excised from pcB-MAhR and pBS-mp65 (murine p65), into the pcDNA3 vector. The 2.7-kb fragment upstream of the Pai-2 transcription start site was generated by PCR (primers 5′-agaatgTTGGAACATCAGGATGATCTCGGATGAG-3′ and 5′-ccatgggGTCAGACACACAGAAATGCCTC-3′) using pGL4-Pai-2 (–2.7 kb) as a template and cloned into the pBS vector. After sequencing, the construct was cleaved with HindIII/NcoI, and the isolated insert was cloned into the HindIII/NcoI-digested pGL4.10 (Promega) to produce pGL4-Pai-2 (–2.7 kb) with NdeI/EcoRV. pGL4-Pai-2 (–0.1 kb) was generated in a similar manner, using primers 5′-GATGTCTTTATATGAAATGTGAATCAATCCCC-3′ and 5′-cactggtGTCGACACACAGAAATGCCTC-3′; pGL4-Pai-2 (–0.55 kb C/EBPβ mutant) was generated by site-directed mutagenesis using a Sculptor in vitro mutagenesis system (Amersham) with pGL4-Pai-2 (–0.55 kb) as a template and primer pair 5′-GATTTAAATTGGAAGGGCTAAATTCTTGAATTTTGAGCTTCAAATTTTAACC2′-3′.

RNA preparation and reverse transcription PCR (RT-PCR). Total RNA was prepared using Isogen (Nippon Gene, Tokyo) according to the manufacturer’s protocol. cDNA synthesis from 1 µg total RNA was carried out using SuperScript II reverse transcriptase (Invitrogen, United States). Real-time PCR was performed using an ABI7300 real-time PCR system (Applied Biosystems) and SuperScript III reverse transcription kit (Invitrogen, United States). Each sample was normalized to the expression of β-actin as a control. The primer sequences were as follows: Pai-1, 5′-CCTCATGCTGGACTTCTCTCA-3′ and 5′-GGGAAGTATGAGACACAAACTAC-3′; Bel-2, 5′-GTTGTCGAGAAGCCTTTACG-3′ and 5′-GGTCTTCCAGGCAGAAGAATG-3′; Arnt, 5′-TTCTATGTCCTCCTCCACATC-3′ and 5′-GGTCCTGCCGTACTCTTTGG-3′; AhR, 5′-TTCTATGTCCTCCTCCACATC-3′ and 5′-CATCTGGTTATCTGCTGAT-3′; Mmp-8, 5′-CACACACACGTGCTGTTACCCAC-5′ and 5′-GAGTCAGAGCTGTCATCC-3′; AhR repressor, 5′-CCGGCCGCTAATGAGGACGC-3′ and 5′-CTCAACCCACAGGGAACATCGGT-3′; IL-1β, 5′-CTGAGAGAGATTCTGACATGCAAC-3′ and 5′-GGATGTCTCTCCTACTGACGAC-3′; TNF-α, 5′-GTTGAGGCCACCTGCTGAC-3′ and 5′-TGTGGATTAGCTGCTGAACT-3′; COX-2, 5′-GTCATGATGCTGATGATCCATG-3′ and 5′-GGATGTGTTAGCTGCTGAACT-3′; Nqo1, 5′-GTCCACACACCACTGATGACC-3′ and 5′-GTTTATGTTTTATGAAGGATC-3′.

PCR experiments were performed using a dual-luciferase reporter assay system according to the manufacturer’s protocol (Promega), with some modifications. RAW 264.7 cells (2.0 × 10⁶ cells/well) were plated in 24-well plates 24 h prior to transfection. Cells were cotransfected with 100 ng pGL4-Pai-2 (various lengths in kilobases) (see “Plasmids”). 1 ng Renilla luciferase (as an internal control), and 1 ng pCDNA-p65 and/or pCDNA-AhR using FuGENE HD transfection reagent (Roche) according to the manufacturer’s protocol. All cells were incubated for 12 h at 37°C after transfection, treated with 10 ng/ml LPS, and incubated for an additional 6 h.

Reporter assays. AhR WT and AhR KO mice. PEMs were stimulated with 10 ng/ml LPS for 60 min and then fixed with formaldehyde for 10 min. The cells were lysed and Western blot analysis was performed.

ChIP assays. Chromatin IP (ChIP) assays were performed with PEMs from AhR WT and AhR KO mice. PEMs were stimulated with 10 ng/ml LPS for 60 min and then fixed with formaldehyde for 4 h at 4°C. The reaction mixture was supplemented with 20 µl of protein A-agarose beads (Amersham). After being incubated for an additional 1 h at 4°C, the beads were washed three times with IP buffer containing protease inhibitor cocktail and resuspended in sodium dodecyl sulfate (SDS) sample buffer. The communoprecipitated proteins were resolved by SDS-polyacrylamide gel electrophoresis (PAGE), and Western blot analysis was performed.
TGG-3' for the NF-κB binding site of Pai-2, 5'-TGAGGTAGGTGGTGGCAG ATTAC-3' and 5'-CCCTCCACACAGCTTTTTC-3' for mPai-2 TATA, 5'- CGGAGGGTAGTTCCATGAAA-3' and 5'-CAGGGCTTTTACCCCGGAA A-3' for the NF-κB binding site of mCox-2, and 5'-CGCAACTCACTGAAGC AGAG-3' and 5'-TCTTTCGTGACAGAGTCTC-3' for mCox-2 TATA. The antibodies used were as follows: anti-AhR serum, preimmune serum, anti-p65, and anti-PolII antibodies (Santa Cruz).

Western blot analyses. Cells were dissolved in SDS sample buffer, and proteins were separated by SDS-PAGE for Western blot analysis. The proteins were then transferred to polyvinylidene difluoride membranes and blocked in 3% skim milk for 30 min. Each antibody was used as a primary reagent, and after being washed three times with Tris-borate-EDTA containing 0.1% Triton X-100, membranes were incubated with species-specific horseradish peroxidase-conjugated secondary antibody (Zymed). The protein-antibody complexes were visualized by using an enhanced chemiluminescence detection system (Amersham) according to the manufacturer’s recommendations. Nuclear extracts were prepared by a standard method (25). The antibodies used were as follows: anti-Arnt serum (28); anti-AhR (Biomol); anti-Pai-2, anti-p65, and antilamin antibodies (Santa Cruz); and antitubulin antibody (Sigma).

RESULTS

High susceptibility of AhR-deficient mice to LPS-induced endotoxin shock. To investigate the function of AhR in acute inflammation in vivo, we performed studies of experimental LPS-induced endotoxin shock. For these studies, 10-week-old AhR WT and AhR KO mice were injected intraperitoneally with 20 mg/kg LPS. After 24 h, while all of the AhR WT mice survived, most of the AhR KO mice (80%) had died (Fig. 1A). These data indicate that AhR-deficient mice were highly susceptible to LPS-induced endotoxin shock. To explain the increased sensitivity of AhR KO mice to septic shock, the plasma concentrations of several inflammatory cytokines were measured 2 h after LPS challenge. Consistent with the enhanced susceptibility of AhR KO mice to the LPS treatment, AhR KO mice had marked increases in plasma IL-1β, IL-18, and TNF-α levels (P < 0.001), with modest increases in IL-6 and IFN-γ (Fig. 1B). In contrast, there was no difference in plasma IL-12p70 levels (Fig. 1B). Administration of 3MC, an AhR ligand, before LPS treatment (30 mg/kg) made the AhR WT mice significantly more resistant to septic shock than the mice that were not treated with 3MC (P = 0.002) (Fig. 1C). Together with the fact that there was essentially no effect of 3MC on AhR KO mice, these results suggested that activated AhR could play an anti-inflammatory role.

Increased susceptibility of mice with AhR KO macrophages to LPS-induced endotoxin shock. Since macrophages play an important role in sensitivity to LPS toxicity, we generated mice with macrophages deficient in AhR [AhRflox/–;LysM Cre (ΔAhR Mac) mice] to evaluate the contribution of macrophages to the LPS hypersensitivity of AhR KO mice. When ΔAhR Mac and control mice (AhRflox/–) were injected intraperitoneally with 25 mg/kg LPS, most of the ΔAhR Mac mice (80%) had died at 48 h after LPS challenge, while 60% of the control mice survived (P = 0.03) (Fig. 2A). Together with the previous results, these data showed that dysfunctional AhR-deficient macrophages are one of the main causes of LPS hypersensitivity in AhR KO mice.

Elevated IL-1β secretion from AhR KO BMDM in response to LPS. To further investigate the cause of the aberrant cytokine secretion by LPS-challenged AhR KO mice, we next asked if there were any differences in the production of proinflammatory cytokines by AhR WT and AhR KO mouse BMDM in response to LPS stimulation. Macrophages from the bone marrow of AhR WT and AhR KO mice were challenged with 10 ng/ml LPS for 8 h, and then the levels of TNF-α and IL-1β in the culture medium were assessed by ELISA. Compared to the levels in AhR WT BMDM, the levels of IL-1β secretion by AhR KO BMDM were markedly elevated, along with slight increases in TNF-α, in response to LPS treatment (P < 0.001) (Fig. 2B, left). However, IL-1β mRNA levels were not altered between AhR WT and AhR KO BMDM (Fig. 2C, left). These data indicated that AhR deficiency markedly increased IL-1β accumulation due to its enhanced secretion rather than its increased synthesis.

Expression of AhR-dependent genes in macrophages. We next performed microarray analysis of AhR WT and AhR KO mouse macrophages to comprehensively investigate the AhR-
These genes were significant because they had been reported to negatively regulate IL-1β secretion by inhibiting the activity of caspase-1 (5, 10). Consistent with the notion that the enhanced secretion of IL-1β is due to the activation of caspase-1, treatment with the caspase inhibitors Z-YVAD-FMK and Z-VAD-FMK markedly reduced the secretion of IL-1β in AhR KO BMDM (Fig. 3A). To confirm their reduced expression in AhR KO BMDM, Pai-2 and Bcl-2 mRNA expression levels were determined by real-time RT-PCR in AhR WT and AhR KO BMDM (Fig. 3B). Figure 3B shows that Pai-2 and Bcl-2 mRNA expression levels were clearly reduced in AhR KO BMDM. To investigate whether the increased IL-1β secretion in AhR KO BMDM was due to their reduced Pai-2 and Bcl-2 expression, the expression of these proteins was supplemented in AhR KO BMDM by infection with adenoviral vectors expressing hPai-2 and hBcl-2 (Fig. 3D).

Arnt is not required for enhancement of LPS-induced Pai-2 expression by AhR. It has been reported that LPS stimulation induces Pai-2 expression (21, 26). Figure 4A and B show that the induction of both Pai-2 mRNA and protein expression was remarkably reduced in AhR KO macrophages compared with the levels in AhR WT macrophages. Interestingly, AhR mRNA and protein expression levels were also induced by LPS stimulation (Fig. 4A and B). In response to various PAHs, AhR is known to act, in most cases, as a transcriptional activator, in heterodimer formation with Arnt. Although the mouse Pai-2 promoter does not have any obvious XRE sequences (GCGTG) in its regions 5 kb upstream and down-

AhR suppresses IL-1β secretion in macrophages

AhR regulates Pai-2 gene expression by a noncanonical mechanism. Consistent with these observations, macrophage-specific conditional deletion of Arnt did not significantly alter the sensitivity to LPS treatment (Fig. 4F).

DNA elements regulating Pai-2 gene expression. We were interested in further investigating how AhR regulates Pai-2 gene expression in macrophages. It has been previously reported that LPS-induced Pai-2 expression requires NF-κB activation (21) and that AhR and p65 physically interact with each other (31). With those results in mind, we constructed a reporter gene by fusing a 2.7-kb sequence upstream of the mouse Pai-2 transcription start site to the luciferase gene (see Fig. S2 in the supplemental material). This 2.7-kb Pai-2 reporter gene contained a previously reported NF-κB site (21). When the AhR expression vector alone was transfected into RAW 264.7 cells, it did not enhance LPS-induced reporter gene expression. In contrast, cotransfection of both AhR and p65 did (Fig. 5A). To identify the sequence responsible for enhancing the LPS-induced activation of the reporter gene, we constructed an 0.8-kb Pai-2 reporter gene by deleting the sequence from −2.7 to −0.8 kb, which contained the previously reported NF-κB site (see Fig. S2 in the supplemental material). With this 0.8-kb Pai-2 construct, the addition of AhR and p65 no longer enhanced the activity in response to LPS treatment (Fig. 5A), indicating that the sequence between −0.8 and −2.7 kb, containing an NF-κB site, is responsible for enhancing Pai-2 gene activation in response to AhR and NF-κB.

Further downstream, we noticed the presence of a putative C/EBPβ binding sequence (around 250 base pairs upstream of the transcription initiation site), which has been reported to be responsible for LPS-induced activation of the gene (4). Deletion or point mutation of this sequence was found to abrogate the ability of LPS to induce this gene, indicating that this C/EBPβ binding site functions as an enhancer sequence in the LPS response (see Fig. S2 in the supplemental material).

Recruitment of transcription factors necessary for LPS-induced Pai-2 expression. When macrophages were treated with LPS, p65 translocated from the cytoplasm into the nucleus independently of AhR (Fig. 5B), as reported previously. However, without AhR, ChIP revealed that p65 was not recruited to the enhancer sequence in the Pai-2 gene, which contains an NF-κB site (Fig. 5E). In WT macrophages, nuclear-translocated p65 was only recruited to the enhancer sequence of the Pai-2 gene together with AhR. PolII was concomitantly recruited to the TATA sequence of the Pai-2 gene in AhR WT but not AhR KO macrophages. Surprisingly, we observed that LPS induced AhR binding to the Pai-2 NF-κB site, as shown by ChIP using an anti-AhR antiserum. Co-IP assays revealed that AhR and p65 interacted in macrophages (Fig. 5C), consistent with a previous report (31). On the other hand, expression of the Cox-2 gene is known to be activated by LPS through recruitment of p65 to its NF-κB binding site, and this occurs independent of AhR (Fig. 5D), with concomitant binding of PolII to the transcription initiation site (TATA) of the Cox-2 gene (Fig. 5E). AhR was not recruited to the Pai-2 promoter by ChIP assay (data not shown), consistent with normal Pai-2 expression in the macrophages from Arntflox/::LysM Cre mice (Fig. 4D).

As shown in Fig. S3 in the supplemental material, the CCAAT box sequence in the Pai-2 gene was recognized by C/EBPβ in an LPS-dependent manner in both AhR WT and KO macrophages. This binding of C/EBPβ to the Pai-2 pro-

stream of the transcription start site, we were interested in determining whether Arnt was also involved in the inducible expression of Pai-2 by LPS. Other AhR target genes identified by the microarray analysis, e.g., the matrix metalloproteinase (Mmp-8) gene and the NAD(P)H:quinone oxidoreductase 1 (Nqo1) gene (Table 1), have characteristic XRE sequences in their promoter regions and were also induced by 3MC. As expected, the induction of their expression was greatly reduced in AhR KO and Arnt small interfering RNA (siRNA)-treated macrophages (Fig. 4E; also see Fig. S1 in the supplemental material). In stark contrast, the expression of Pai-2 was not much different in Arnt KO and Arnt siRNA-treated macrophages, indicating that Arnt is not involved in regulating Pai-2 gene expression (Fig. 4D; also see Fig. S1 in the supplemental material) and that AhR regulates Pai-2 gene expression by a noncanonical mechanism. Consistent with these observations,
moter might explain the weak LPS-induced activation of Pai-2 gene expression in AhR KO macrophages (Fig. 4A; also see Fig. S3 in the supplemental material), as described in the previous section.

The requirement of the functional domains of AhR for AhR-dependent Pai-2 expression. To determine the functional domains of AhR for AhR-dependent Pai-2 expression, we investigated the Pai-2 expression in ANA-1 cells, which were transfected with various AhR mutants (Fig. 6). Compared with the levels in ANA-1 cells transfected with full-length AhR, we observed much lower levels of expression of Pai-2 in the ANA-1 cells transfected with AhR NLSm (a mutant located predominantly in the cytoplasm) (Fig. 6B, bars 3, 4, 11, and 12). On the other hand, transfection with AhR CA (a constitutively active mutant located predominantly in the nucleus) gave a result for Pai-2 expression comparable to that of the transfection with full-length AhR (Fig. 6B, bars 3, 4, 7, and 8). These results indicated that nuclear AhR functions in AhR-dependent Pai-2 expression. The fractionation of AhR indicated that a small but significant amount of AhR existed in the nucleus without treatment with ligands such as 3MC, in contrast with the large amount in the cytoplasm (Fig. 5B), consistent with the previous report that AhR has functional nuclear localization signal and nuclear export signal sequences and shuttles between the cytoplasm and nucleus. It is reported that when nuclear export is inhibited by trichomycin B or phosphorylation at S68, AhR accumulates in the nucleus (12). Therefore, it could be considered that in macrophages, AhR is in-

FIG. 4. Arnt is not required for LPS-induced enhancement of Pai-2 expression. (A) Relative Pai-2 and AhR mRNA expression levels in AhR WT and AhR KO PEMs 4 h after treatment with (black or gray bars) or without (white bars) LPS (10 ng/ml). (B) Immunoblot analysis of Pai-2 and AhR expression in AhR WT and KO PEMs after a 16-h incubation with LPS (10 ng/ml). (C) Immunoblot analysis of Arnt in Arntfloxflox and Arntfloxflox::LysM Cre PEMs. (D) Relative Pai-2 mRNA expression levels 4 h after incubation of Arntfloxflox (black bar) and Arntfloxflox::LysM Cre (hatched bar) PEMs with LPS (10 ng/ml). (E) Left, relative expression levels of Mmp-8 and Nqo1 mRNA in Arntfloxflox (black bar) and Arntfloxflox::LysM Cre (hatched bar) PEMs treated with DMSO (white bars) or 3MC (black or hatched bar) (1 μM). Right, relative expression levels of Mmp-8 and Nqo1 mRNA in AhR WT (black bar) and AhR KO (gray bar) PEMs treated with DMSO (white bars) or 3MC (black or gray bar) (1 μM). (F) Survival of Arntfloxflox (Arnt fl−; n = 7) and Arntfloxflox::LysM Cre (Arnt fl−::cre; n = 12) mice after LPS challenge (25 mg/ml). Error bars show standard deviations. involved in Pai-2 expression induced by LPS treatment in the absence of typical AhR ligands (Fig. 4A). The mechanism of AhR's involvement in Pai-2 expression induced by LPS will be investigated in detail. To further address the question of the requirement for the AhR domain in Pai-2 expression, we generated ANA-1 cells stably transfected with AhR/ΔC (an activation domain-deficient mutant) and AhR Y9F (the mutant with attenuated DNA binding) (18). Compared with the expression in stable ANA-1 cells transfected with full-length AhR, neither of the cell lines transfected with AhR ΔC or AhR Y9F significantly expressed Pai-2 (Fig. 6B, bars 3 to 6, 9, and 10). These results indicate that both the activation and DNA binding domains of AhR were required for AhR-dependent Pai-2 expression. Co-IP analysis using these AhR mutants showed that the N-terminal region of AhR (AhR ΔC mutant) interacted with p65 (Fig. 6C).

**DISCUSSION**

AhR was originally found as a transcription factor that was involved in the induction of xenobiotic-metabolizing CYP1A1 by TCDD and other PAHs and has been found to act as a multifunctional regulatory factor in areas ranging from drug metabolism to innate immunity, providing protection against invading xenobiotics. Close investigation of the phenotypes of AhR KO mice revealed that they seem to suffer from morbidity from impaired immunity and easily succumb to bacterial infection. We examined the susceptibility of AhR KO mice to LPS-induced septic shock and found that they were hypersensitive to LPS treatment and had increased secretion of proinflammatory cytokines, such as IL-1β, TNF-α, IL-18, and IFN-γ (Fig. 1A and B). It has been reported that in endotoxic shock, IL-1β and TNF-α are rapidly released and trigger a secondary...
secreted much larger amounts of IL-1.

Consistent with these observations, isolated AhR KO BMDM deficiency is one of the major causes of the enhanced susceptibility to enhanced processing of IL-1β oversecretion in AhR KO macrophages, while no suppressive effect was observed with Bel-2 expression (Fig. 3C). It has been reported that there are several pathways for processing IL-1β that lead to its secretion (16). These results indicate that Pai-2 and Bel-2 are differentially involved in these pathways. Recently, in experiments using ΔIKKβ myeloid mice, Pai-2 has been reported to suppress IL-1β secretion, acting downstream of NF-κB (10).

The IL-1β processing that is regulated by the inflammasome involves caspase-1 (16). Consistent with these observations, treatment with caspase inhibitors, Z-YVAD-FMK and Z-VAD-FMK markedly reduced the secretion of IL-1β in AhR KO BMDM (Fig. 3A). It has also been reported that IL-18 processing is regulated by the same mechanism as IL-1β, which is consistent with the marked increase in plasma IL-18 levels (P < 0.001) observed in LPS-injected AhR KO mice (Fig. 1B).

Stimulation of the inflammasome involving caspase-1 usually requires secondary signals, such as high ATP concentrations. Interestingly, however, the IL-1β oversecretion resulting from AhR deficiency did not seem to require any other stimulation besides LPS, which is in accordance with the report on the IKKβ myeloid mice (10). Further investigation will be required to address the molecular details of Pai-2-regulated IL-1β secretion.

Although it has been reported that Pai-2 mRNA was induced by a typical AhR ligand, TCDD (27), we did not find any obvious XRE sequences (GCGTG) in the 5-kb regions upstream or downstream of the transcription start site of the mouse Pai-2 promoter. However, these promoter regions rendered a reporter gene responsive to LPS (Fig. 5A and E). This sequence search suggested that AhR might not regulate Pai-2 gene expression in the canonical way (i.e., heterodimerized with Arnt) and led us to investigate whether Arnt was involved in LPS-induced Pai-2 regulation. In experiments with Arnt-deficient and Arnt siRNA-expressing macrophages, we demonstrated that AhR enhanced Pai-2 expression in an Arnt-independent manner (Fig. 4D; also see Fig. S1 in the supplemental material). Arnt2 is considered to be another possible alternative (11), but we have previously shown that AhR interacts predominantly with Arnt but not with Arnt2 (27). Therefore, it is highly likely that AhR enhances Pai-2 expression independently of Arnt family proteins (11). It was previously reported that LPS induced Pai-2 expression through activation of NF-κB (21) and that AhR physically interacted with p65 (31) to activate or inhibit gene expression in a context-dependent manner (31). In our reporter gene assay using RAW 264.7 cells, the Pai-2 reporter gene required both NF-κB and AhR for a high level of expression in response to LPS treatment (Fig. 5A). In AhR KO macrophages, LPS treatment induced nuclear translocation of p65 (Fig. 5B), but it was not recruited to the NF-κB-binding site of the Pai-2 gene, which confers LPS inducibility (Fig. 5E), suggesting that AhR is required for recruitment of p65 to this site, which may be a

FIG. 6. Nuclear localization, activation, and DNA binding domains of AhR are required for AhR-dependent Pai-2 expression. (A) Immuno blot analysis of full-length AhR or mutants in LacZ or AhR transformant ANA-1 cells. Paired lanes labeled 1 and 2 show results from experiments using two independent transformants. (B) Relative expression levels of Pai-2 mRNA in ANA-1 cells transfected with LacZ or full-length AhR or mutants. Bars show quantification of the results in the 12 lanes in panel A; error bars show standard deviations. *, P < 0.001; NS, not significant. (C) Interaction of p65 and AhR mutants. Co-IP of p65 and full-length AhR or mutants expressed in 293T cells, using anti-p65 antibody. AhR FL (full-length) comprises amino acids 1 to 805, AhR ΔC comprises amino acids 1 to 544, and AhR CA comprises amino acids 1 to 276 and 419 to 805; in AhR Y9F, Y9 was mutated to F; and in AhR NLSm 37R, 38H, and 39R were mutated to A, G, and S, respectively. inflammatory cascade that is dependent on the transcription factor NF-κB (10). Mice with a macrophage-specific conditional deletion of AhR (AhR<sup>fl</sup>−/−:Lysm Cre) were more susceptible to LPS-induced septic shock than AhR<sup>fl</sup>−/− mice, indicating that the dysfunction of macrophages due to AhR deficiency is one of the major causes of the enhanced susceptibility of AhR KO mice to LPS-induced septic shock (Fig. 2A). Consistent with these observations, isolated AhR KO BMDM secreted much larger amounts of IL-1β and had a slight increase in TNF-α in response to LPS (Fig. 2B). Since IL-1β mRNA levels were not altered between AhR KO and AhR WT BMDM (Fig. 2C), the increased IL-1β secretion is probably not due to the enhanced synthesis but, rather, is likely due to enhanced processing of IL-1β (16).

We thought that this IL-1β oversecretion by AhR-deficient macrophages might provide clues as to how AhR functions as a physiological immunosuppressor. Microarray analyses to comprehensively investigate the AhR-dependent changes in gene expression that were responsible for increased IL-1β secretion revealed that the levels of expression of Pai-2 and Bel-2 mRNA were markedly reduced in AhR KO BMDM, which was confirmed by real-time PCR (Fig. 3B). Reconstitution experiments with adenoviruses showed that only Pai-2 expression could significantly suppress IL-1β oversecretion in AhR KO macrophages, while no suppressive effect was observed with Bel-2 expression (Fig. 3C). It has been reported that there are several pathways for processing IL-1β that lead to its secretion (16). These results indicate that Pai-2 and Bel-2 are differentially involved in these pathways. Recently, in experiments using ΔIKKβ myeloid mice, Pai-2 has been reported to suppress IL-1β secretion, acting downstream of NF-κB (10). The IL-1β processing that is regulated by the inflammasome involves caspase-1 (16). Consistent with these observations, treatment with caspase inhibitors, Z-YVAD-FMK and Z-VAD-FMK markedly reduced the secretion of IL-1β in AhR KO BMDM (Fig. 3A). It has also been reported that IL-18 processing is regulated by the same mechanism as IL-1β, which is consistent with the marked increase in plasma IL-18 levels (P < 0.001) observed in LPS-injected AhR KO mice (Fig. 1B).

Stimulation of the inflammasome involving caspase-1 usually requires secondary signals, such as high ATP concentrations. Interestingly, however, the IL-1β oversecretion resulting from AhR deficiency did not seem to require any other stimulation besides LPS, which is in accordance with the report on the IKKβ myeloid mice (10). Further investigation will be required to address the molecular details of Pai-2-regulated IL-1β secretion.

Although it has been reported that Pai-2 mRNA was induced by a typical AhR ligand, TCDD (27), we did not find any obvious XRE sequences (GCGTG) in the 5-kb regions upstream or downstream of the transcription start site of the mouse Pai-2 promoter. However, these promoter regions rendered a reporter gene responsive to LPS (Fig. 5A and E). This sequence search suggested that AhR might not regulate Pai-2 gene expression in the canonical way (i.e., heterodimerized with Arnt) and led us to investigate whether Arnt was involved in LPS-induced Pai-2 regulation. In experiments with Arnt-deficient and Arnt siRNA-expressing macrophages, we demonstrated that AhR enhanced Pai-2 expression in an Arnt-independent manner (Fig. 4D; also see Fig. S1 in the supplemental material). Arnt2 is considered to be another possible alternative (11), but we have previously shown that AhR interacts predominantly with Arnt but not with Arnt2 (27). Therefore, it is highly likely that AhR enhances Pai-2 expression independently of Arnt family proteins (11). It was previously reported that LPS induced Pai-2 expression through activation of NF-κB (21) and that AhR physically interacted with p65 (31) to activate or inhibit gene expression in a context-dependent manner (31). In our reporter gene assay using RAW 264.7 cells, the Pai-2 reporter gene required both NF-κB and AhR for a high level of expression in response to LPS treatment (Fig. 5A). In AhR KO macrophages, LPS treatment induced nuclear translocation of p65 (Fig. 5B), but it was not recruited to the NF-κB-binding site of the Pai-2 gene, which confers LPS inducibility (Fig. 5E), suggesting that AhR is required for recruitment of p65 to this site, which may be a...
crossing point between AhR and NF-κB signaling pathways. In WT macrophages, AhR and p65 were recruited to the same DNA sequence by the LPS treatment (Fig. 5E), and they interacted directly (Fig. 5C and 5D), leading to the recruitment of PolII to the TATA sequence of the transcription initiation site. In contrast, p65 was recruited to the Cox-2 promoter in response to LPS treatment in AhR KO macrophages. The detailed molecular basis for how p65 binds differently to the Pai-2 and Cox-2 genes remains to be investigated.

It was also reported that AhR interacts with RelB on chemokine promoters, such as IL-8, in response to TCD treatment, enhancing their expression (33). Although an AhR-RelB binding DNA sequence, designated RelBAhRE (GGGTGC), was found near the NF-κB site in the Pai-2 promoter, the expression of the Pai-2 (2.7 kb) Luc reporter gene was not enhanced by RelB and AhR coexpression (data not shown), suggesting that RelB may not function as a partner for AhR in inducing Pai-2 expression. Since the AhR DNA binding activity was suggested by the results of the experiment using the AhR Y9F mutant to be required for AhR-dependent Pai-2 expression (Fig. 6B, bars 3, 4, 9, and 10), the possibility could be raised that an AhR and p65 heterodimer might work as a transcription factor by binding the RelBAhRE sequence. However, the experiments using the reporter gene containing a tandem arrangement of four RelBAhRE sequences did not show enhanced expression of the reporter gene expression with coexpression of AhR and p65. It remains to be investigated in detail how AhR and p65 activate the Pai-2 promoter. AhR has been reported to have the nuclear localization signal and nuclear export signal sequences and to shuttle between nucleus and cytoplasm. Inhibition of nuclear export of AhR by trichomicyn B or phosphorylation reportedly leads to the accumulation of AhR in the nucleus (12). Consistent with these findings, a small part of AhR was observed in the nuclei of WT macrophages under normal conditions. Upon treatment with LPS, nuclear AhR should accumulate due to phosphorylation downstream of the LPS signaling pathway or p65, reported to be translocated into the nucleus (21), should be recruited to the Pai-2 promoter with the nuclear AhR.

Recently, there have been growing lines of evidence that AhR plays a crucial role in differentiation of the Th cell subsets Th1, Treg, and Th17 from naïve CD4 T cells. It was reported that differentiation of these regulatory T cells from AhR KO naïve T cells was significantly impaired under their respective polarizing conditions. AhR is reported to be highly induced under these conditions (14, 20, 23, 32), and AhR ligands further stimulated the tendency to their respective differentiations by molecular mechanisms that are largely unknown. In macrophages, AhR was also induced by LPS treatment (Fig. 4A and B) and negatively regulated the secretion of certain inflammatory cytokines, such as IL-1β and IL-18, most likely through the expression of Pai-2. Since AhR is a ligand-activated transcription factor and is known to be ubiquitously expressed in immune cells (13), this raises the possibility that an appropriate AhR ligand may be useful for treating patients with inflammatory disorders.
